## Review of Lecture 5

- Persistence Length and its significance
- Microtubules and Actin filaments are polymers of tubulin and actin monomers
- Dynamics of Microtubule and Actin Filaments
- Example of force generation by microtubule and actin filament
- Measurement of force generated by microtubule and actin filament

## Measurement of force generated by microtubule and actin filament

- Forces generated by biofilaments are typically of the order of pN
- Modern Techniques such as Optical Tweezers and AFM are used for measurement of such forces

# Measurement of Forces using Optical Tweezers

# Proteins and their structures

- Proteins perform their function by folding into different shapes
- Proteins are sequence of amino acids
- Given a sequence of amino acids can be predict the structure of the protein?

# Protein Structures and Folding

- Proteins are sequence of amino acids
- **Given a sequence of amino acids can be predict the structure of the protein?**
- Classical mechanics tell us that protein would prefer the structure/conformation which minimizes energy
- However, this is not true when thermal fluctuations are present

# Protein Structures are free energy minimizers

- In presence of thermal fluctuations, a protein folds into the structure which minimizes free energy, out of all the possible ways that a particular chain of amino acids can fold up
- What is free energy?
- Helmholtz free energy
- Gibbs free energy

$$A = U - TS$$

$$G = H - TS$$

$$H = U + pV$$

# Free Energy

- Free energy=Energy- Temperature x Entropy
- Free energy can be minimized by either decreasing energy or increasing entropy
- In order to calculate free energy we have to calculate entropy
- **What is entropy? How to calculate entropy?**

# Entropy

- Entropy is a measure of the microscopic degeneracy of a macroscopic state (“macro-state”)
- In other words, entropy can be computed by counting the number of possible microscopic arrangements/states (“micro-states”) for a given macroscopic state (“macro-state”)

$$S = k_B \ln W$$

$W$  is the number of possible microscopic arrangements (or “micro-states”)

# Entropy

# Micro-state and Macro-state

- Consider a protein that can exist in two **structural states**. For example open (1) and closed (2)

# Micro-state and Macro-state

- However, due to thermal fluctuations, these structural states consists of enormous number of **conformations states**, where a conformational state is a set of positions of all the atoms
- Structural states  $\Rightarrow$  “Macro-states”
- Conformational states  $\Rightarrow$  “Micro-states”

# Micro-state and Macro-state

- We know that probability of finding protein any microstate  $i$  or  $j$  is given by Boltzmann law

$$p_i = \frac{1}{Z} e^{-\frac{U_i}{k_B T}} \quad p_j = \frac{1}{Z} e^{-\frac{U_j}{k_B T}}$$

- What is the probability of finding protein in a given macrostate?
- The probability of finding protein in a given macrostate is given sum of all  $p_i$  or  $p_j$

## Micro-state and Macro-state

- Thus, Probability of finding in a macrostate  $X$  is given by

$$p(X) = \sum_{i \in X} p_i = \sum_{i \in X} \frac{1}{Z} e^{-\frac{U_i}{k_B T}}$$

- Using relation  $G = -k_B T \ln Z$  between partition function and free energy it can be shown that

$$p(X) = \frac{1}{Z} e^{-\frac{G(X)}{k_B T}}$$

- Similar to Boltzmann formula for microstate, energy replaced by free energy of macrostate

# Proof of $G = -k_B T \ln Z$

$$\left. \begin{aligned} G &\equiv \langle U \rangle - TS \\ \langle U \rangle &= \sum_{i=1}^N U_i P_i \\ S &= -k \sum_{i=1}^N p_i \ln p_i \end{aligned} \right\} \Rightarrow G = \sum_{i=1}^N U_i P_i + kT \sum_{i=1}^N p_i \ln p_i = \sum_{i=1}^N P_i \left\{ U_i + kT \ln p_i \right\}$$

$$\left. \begin{aligned} P_i &= \frac{1}{Z} \exp \left[ -\frac{U_i}{kT} \right] \end{aligned} \right\}$$

$$\Rightarrow G = \sum_{i=1}^N \frac{1}{Z} \exp \left[ -\frac{U_i}{kT} \right] \left\{ U_i + kT \ln \left( \frac{1}{Z} \exp \left[ -\frac{U_i}{kT} \right] \right) \right\} = \frac{1}{Z} \sum_{i=1}^N \exp \left[ -\frac{U_i}{kT} \right] \left\{ U_i - kT \ln Z - U_i \right\}$$

$$\left. \begin{aligned} Z &= \sum_{i=1}^N \exp \left[ -\frac{U_i}{kT} \right] \end{aligned} \right\}$$

$$\Rightarrow G = -kT \ln Z \Rightarrow Z = \exp \left( -\frac{G}{kT} \right)$$

## So far...

- Proteins can exist in many structural states “macrostates”
- Each “macrostate” consists of many “microstates”
- “macrostate” with minimum free energy is preferred
- $G = H - TS$ ,  $G = -k_B T \ln Z$  and  $S = k_B \ln W$
- Probability of finding a macrostate  $X$  is given by

$$p(X) = \frac{1}{Z} e^{-\frac{G(X)}{k_B T}}$$

# HP models of protein folding

- Consider a protein consisting of eight amino acids consisting of H and P
- The sequence of the amino acids is HPHHHHHP
- Suppose that this protein can fold into five possible structures such that energy increases by  $\varepsilon$  for every contact of H with either P or solvent molecule
- Suppose these structures can be broadly classified into two macroscopic states “Open” and “Packed”

# HP models of protein folding

- What will be the structural state of the protein at temperature  $T$  i.e. Open or Packed?

# HP Models of Protein Folding

$$G_{open} = 13\varepsilon - k_B T \ln 3$$

$$G_{packed} = 11\varepsilon - k_B T \ln 2$$

Open will be preferred as long as  $G_{open} < G_{packed}$

Or,

$$13\varepsilon - k_B T \ln 3 < 11\varepsilon - k_B T \ln 2$$

Or,

$$T < \left( \frac{\varepsilon}{k_B} \right) \left( \frac{2}{\ln(\frac{3}{2})} \right)$$

# Another Toy Models of Protein Folding

- Consider a protein consisting of three amino acids A, B and C connected with bonds of equal length
- This protein is placed on a square grid such that only A and C are free to rotate in a plane such that the bonds are always aligned along the grid lines

Colored lines denote that space is inhomogeneous

## Another Toy Models of Protein Folding

- Bending energy of the protein is given by

$$\epsilon = A(1 + \cos\theta_{AC})$$

**Whether the structural state of the protein will be bent or straight?**

- What is the energy of the straight conformation?
- What is the energy of the bent conformations?
- Classical Mechanics: It should be in straight state

# Number of Straight and Bent conformations

Straight

Bent

- No. of straight conformations=4
- No. of bent conformations=8

# Calculate Average Bending Energy

$$\epsilon = A(1 + \cos\theta_{AC})$$

Straight

Bent

$$\epsilon_{Straight} = 0$$

$$\epsilon_{bent} = A$$

# Calculate Entropy

$$S = k_B \ln W$$

Straight

Bent

$$W_{straight} = 4$$

$$S_{straight} = k_B \ln 4 = 1.4 k_B$$

$$W_{bent} = 8$$

$$S_{bent} = k_B \ln 8 = 2.1 k_B$$

# Calculate Free Energy

Straight

Bent

$$G_{Straight} = 0 - 1.4 k_B T$$

$$G_{bent} = A - 2.1 k_B T$$

# Bent or Straight

$$G_{Straight} = 0 - 1.4 k_B T$$

$$G_{bent} = A - 2.1 k_B T$$

- When  $A = 0.1 k_B T$  bent structure is preferred
- However, when  $A = 1.5 k_B T$ , straight structure is preferred

# Summary

- Proteins and their structures
- Proteins are free energy minimizers
- Microstate and Macrostate
- Relations  $G = H - TS$  and  $G = -k_B T \ln Z$
- $S = k_B \ln W$
- HP model and a Toy model of protein folding
